

Gomphrena species

Propagation

PRE-TREATMENT – No pre-treatment is required for this species.

SOWING – Best sown in Autumn or Spring when temperatures are between 18 - 22°C.

Use a good quality seed raising media.

Water the media and sprinkle the seeds over the surface – do not bury too deeply!

Water with mist spray to avoid seed dislodging.

Keep warm and moist, in a warm shaded or part shaded position - don't allow seeds to dry out and avoid waterlogging media.

Seeds should start spouting in 2 - 4 weeks but can take longer depending on conditions.
